I claim:

- 1. A measuring apparatus for determining a thickness of paper sheets or similar flat products, wherein the products to be measured are continuously fed on a counterpressure surface, the measuring apparatus comprising a measuring roller resting on the products to be measured above the counterpressure surface, wherein the measuring roller is rotatably mounted on a lever, and wherein the lever is pivotable about a shaft whose rotary movement is evaluated by an angle pickup which converts the rotary movement into an electrical voltage change.
- 2. The measuring apparatus according to claim 1, wherein the lever is mounted so as to be pivotable against a compression spring for damping overshooting.
